

Get to know the TWR-S08LH64

TWR-S08LH64-KIT Freescale Tower System

The TWR-S08LH64 module is part of the Freescale Tower System, a modular development platform that enables rapid prototyping and tool re-use through reconfigurable hardware. Take your design to the next level and begin constructing your Tower System today.

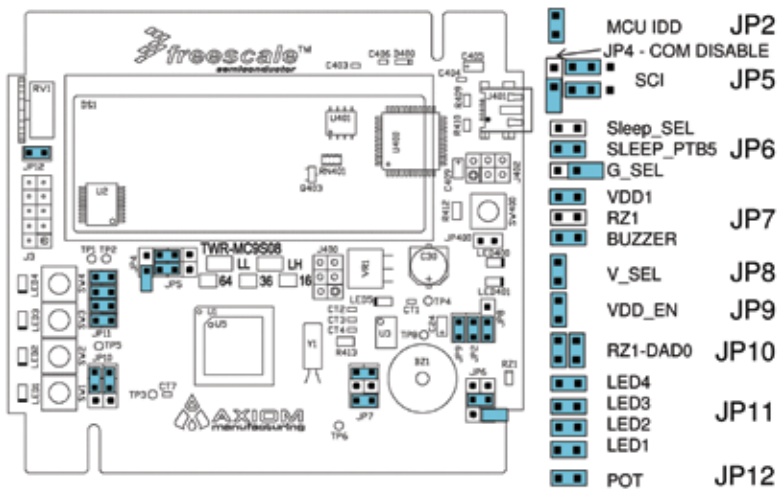

Figure 2
The jumper settings on the MCU Tower module are set to enable operation of the Quick Start application programmed into the flash memory of the MC9S08LH64 MCU.

TWR-S08LH64 — Lab Tutorials 1 and 2 (sheet 1 of 2)

Introduction

The MC9S08LH64 device is Freescale's low-power microcontroller with an integrated liquid crystal display (LCD) driver and 16 bit ADC with a differential input channel and up to 8 single-end inputs. TWR-S08LH64 contains on-board analog input channels that allows developers to explore the capabilities of the powerful new ADC module. It also contains an on-module display that allows developers to explore software development using the integrated LCD driver. This Lab Tutorial guide is designed to get you ready to develop your next measurement and display application using the MC9S08LH64 within minutes.

Note: This Lab Tutorial can be followed once the steps in the Quick Start Guide, installing all of the software and documentation, have been finalized.

STEP
1

Lab Using Quick Start Code, Open CodeWarrior and the Project

This lab will highlight the capabilities of the MC9S08LH64 microcontroller with the application provided by the Quick Start Lab. Pushing switch SW2 will step you through these four states.

State 1. Low power operation with time display
State 2. Potentiometer vs. light sensor comparison

State 3. Accelerometer demo, X, Y and Z output to SCI

State 4. ADC demo: When in the ADC demo, pushing SW4 will increment the channel converted and displayed

1. Install software and tools as directed in the Quick Start Guide.
2. Open CodeWarrior for microcontrollers. From Windows start menu. You can locate it using "Programs > Freescale CodeWarrior > CW for Microcontroller 6.3 > CodeWarriorIDE"
3. Choose the "Start Using CodeWarrior" button.
4. Using CodeWarrior, click **File > Open** and open the **PE_LH64 Quick_Start.mcp** file from the directory on your c:\ where you unzipped the compressed projects. This is the Quick Start project which uses CodeWarrior's Processor Expert for device initialization.

STEP
2

Explore Project Window of Quick Start Code

Figure 3 illustrates the "Processor Expert" and "Files" tabs.

Figure 3

There are four tabs in the project window: File, Link Order, Target and Processor Expert. Each tab displays the contents of the project with respect to the context of the tab selected. The user code is displayed in the Files tab.

STEP
3

Set Up TWR-S08LH64 Module

1. Connect the 10-pin connector to the 10-pin header on the module labeled COM PORT and J3 (see Figure 4). During states 2, 3 and 4, data is sent from the SCI port on the MCU to the terminal console on your computer.
2. Connect an RS232 cable from the DB9 pigtail to your computer serial port.

Figure 4

STEP
4

Start P&E Toolkit Application and Enter the Programmer/Debugger

1. Open P&E Multilink Toolkit Launch Pad and Terminal Window. From the Windows start menu, select "Programs > P&E Embedded Multilink Toolkit > Toolkit Launchpad"
2. Start a terminal console and configure your computer's com port for 19200 baud, 8 bit, 1 stop, no parity.
3. Using CodeWarrior, compile and program the MC9S08LH64 microcontroller with the application by clicking the "Debug" button or F5 on your keyboard, launching the programmer and the open source BDM debugger.
4. If the MCU is in low-power stop mode you may see the message "There is currently no communication." Click "OK." Re-establish communication by hitting SW2 and under the Component > Set Connection, set HCS08 and FSL open source BDM. This re-establishes BDM communications.

Figure 5

5. When the message, "Loading a new application will stop execution of the current one" appears, click "OK."

Figure 6

6. When the message, "The debugger is going to mass erase the non-volatile memory of the current device, then reprogram the application" appears, click "OK."

Figure 7

STEP
5

Debugger Window

A new debugger environment will open. From the main menu, choose "Run > Start/Continue" or press the button. The program will be executed in real time.

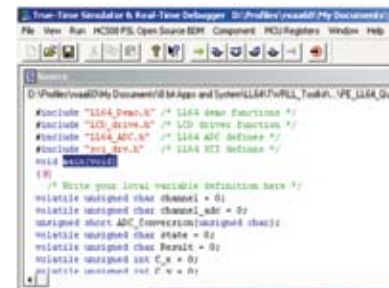

Figure 8

Lab
1

State
1

Clock Display State

Upon power-on or reset, the LCD will flash all segments on, then off, the buzzer will sound, then the display will read "9LH64" and "CL." Next, it enters a low-power time/day display mode. The display is initialized with a clock value, the current temperature and a day of the week. The MCU will keep track of time with the TOD module running off the 32.768 watch crystal. The temperature and battery level are measured with the ADC16 and displayed.

Figure 9

Highlighted features include the ADC16 measurement of the internal temperature sensor, bandgap voltage, the TOD and LCD module operations in low-power stop mode. While in stop mode, the LCD blinking function is operational.

Display and Control Features

- 1) Press and hold SW2 for longer than two seconds to toggle the display view between displaying the temperature or displaying the seconds value in the upper two display digits.
- 2) Press and hold SW1 to enter set time and day mode. When you do this the display temporarily displays "CL" then "SE" for Clock Set and the hours digit begins flashing. Set Hour: Press SW1 to decrement and SW2 to increment.

Press and hold for two seconds both SW1 and SW2 to step to the Set Minute state.

Set Minute: Press SW1 to decrement and SW2 to increment.

Press and hold for two seconds both SW1 and SW2 to step to the Set Day state.

Set Day: Press SW1 to decrement and SW2 to increment.

Press and hold for two seconds both SW1 and SW2 to exit the set clock mode.

The display will return to the normal display of the new time and temperature.

Measure current: To measure the average current of the MCU, remove the jumper "MCU IDD" JP2 and place a current meter between the two pins of JP2. Reset the TWR_S08LH64 module with the Reset button. You should measure less than 3 micro-amps

Wake up time: The MCU is currently waking up every second and updating the seconds counter in the software. To reduce power consumption, the MCU wakeup time could be changed to 60 seconds. This reduces the times the MCU has to wake up, enter run mode and update the time on the LCD display.

In the file LH64_Demo.c the code to enable 60 second wake up is commented out. In the function "void StopClock(void)," comment out the existing line that begins with `void StopClock(void)` and remove the comment `/*` from the next line. After programmed with this new code, the MCU will wake up every 60 seconds. This changes from a second to the match interrupt. Measure the current again and compare. You may have to close the debugger window to enable the lower current mode.

TWR-S08LH64 — Lab Tutorials 1 and 2 (sheet 2 of 2)

Lab 1 **State 2**

Potentiometer vs. Light Sensor State

This state uses two ADC channels to read the position of the potentiometer and the light sensed by RZ1, the on-module light sensor. Press switch SW2 and the program enters Potentiometer vs. Light Sensor state.

The display shows "LI" and the potentiometer value on the large characters on the bottom and the light sensor value on the smaller top right two characters. The third character displays the <, > or = char comparing the POT to the light sensor. The two values are also sent through the SCI port at 19.2 K baud.

1. Launch the "Serial Grapher" utility from the **PEMICRO UTILITY LAUNCH PAD** program.
2. Select your computers com port and set the baud rate to 19200, 8 bits, 1 stop bit, no parity. (Typically COM1)
3. Click "Open Serial Port and Start Demo." Text similar to this should appear in the terminal window:
 "POT = FD Light Sensor Z1 = 56 "
 "POT = FD Light Sensor Z1 = 58 "
 "POT = FD Light Sensor Z1 = 65 "
4. The MCU is measuring the RZ1 light sensor across a feedback resistor in an op amp buffer with the dedicated differential input pair DADP0 and DADMO. Adjust the potentiometer and change the light level reaching the light sensor and notice the changes on the display. If ever the values of the pot and the RZ1 are the same the buzzer will sound and the display will show the "=" sign.

Figure 10

Lab 1 **State 4**

ADC Demo State

Press switch SW2 again and enter the ADC demo state. The LCD displays "ADC." The demo does a 16-bit conversion averaged 32 times and displays the lower 12 bits of the 16-bit result in the first three characters as well as the channel number in the two upper right characters. Pushing SW4 will increment the channel converted and displayed.

This mode measures and displays the selected ADC channel while sending the data to the SCI output. Using the same terminal setup as State 2 you will be able to see the text as shown in Figure 12 being displayed in the terminal window. Figure 11 is a short description of each of the columns of the text output. Refer to the LH64 reference manual for detailed description of the registers being reported.

Column	Symbol	Description
1	CFG1	Configuration Register 1
2	PG	Post Calibration Plus-Side Calibration Values
3	CLPD	
4	CLPS	
5	CLP4	
6	CLP3	
7	CLP2	
8	CLP1	
9	CLP0	
10	MG	Post Calibration Minus-Side Calibration Values
11	CLMD	
12	CLMS	
13	CLM4	
14	CLM3	
15	CLM2	
16	CLM1	
17	CLM0	
18	Offset	Calibration Offset Value
19	CHNLA	Channel for Data A
20	DATAA	Result Data A
21	VREFT	VERF Variable

Figure 11

Lab 1 **State 3**

Accelerometer Graphing State

Press switch SW2 and the program enters the Accelerometer Graphing state. This mode uses the 3-axis accelerometer, the ADC and the SCI to measure and output the 3-axis data. Using the same setup as State 2, you will be able to graph the movement of the accelerometer as you move the module. Lab 2 provides a more in-depth accelerometer demo.

CFG1	PG	CLPD	CLPS	CLP4	CLP3	CLP2	CLP1	CLP0	MG	CLMD	CLMS	CLM4	CLM3	CLM2	CLM1	CLM0	Offset	CHNLA	DATAA	VREFT

Figure 12

See Figure 13 for ADC channel assignments.

Press switch SW4 to change the channel and watch the LCD screen and SCI output. Note that the VREF0 channel (0x13) varies since the code is looping, modifying the trim of this voltage reference. This demonstrates the ability to adjust or trim the VREF output voltage.

ADCH	Channel	Input	Pin Control

Figure 13

Lab 2

Accelerometer Demo

This lab will highlight the performance capability of the MC9S08LH64 microcontroller and show how this microcontroller can easily interface with a sensor. It will also detail how to use one of several software utilities included with your TWR-S08LH64 module.

The accelerometer application reads the X, Y and Z axes of the 3-axis accelerometer on the TWR-S08LH64 module using the microcontroller's 16 bit A/D converter. It outputs the raw values of the accelerometer data on the microcontroller's serial communication interface.

Pressing the SW1 switch outputs a rolling average of the raw accelerometer data. Pressing the SW2 switch outputs a filtered version. Pressing the SW3 switch reverts back to the raw data output.

Open and Program MCU with Accelerometer Code

1. Make sure the jumpers are in their default positions.
2. Using CodeWarrior, click **File > Open** and open the **TWR9S08LH64_Accelerometer mcp** file from the directory on your c:\ where you unzipped the compressed projects.
3. Compile the code and program the MCU by clicking on "Debug" button, launching the debugger.
4. When the message, "Loading a new application will stop execution of the current one" appears, click "OK."
5. When the message, "The debugger is going to mass erase the non-volatile memory of the current device, then reprogram the application" appears, click "OK."
6. A debugger environment will open. From the main menu, choose "Run > Start/Continue." The program will be executed in real-time.
7. Launch accelerometer utility from the **PEMICRO TOOLKIT LAUNCH PAD** and select "Accelerometer."
8. Set your computer's Com port, set the baud rate to 19200 and click "Open Serial Port and Start Demo."

Run Demo and Observe Graph

Note the X, Y and Z and C bar graphs and the scope window on the accelerometer graph. If the values are too small to view, highlight a box around the graph data and hit the play button in the graph window. The raw XYZ data is being displayed and the response is very quick.

Press SW2 switch and "averaging" will be enabled. Notice the "C" bar chart or cycle count increase and the smoothing effect on the XYZ data as you move the module.

Figure 16

Press SW1 switch and the FIR filter algorithm begins executing. The cycle count will increase again and the response of the graph will change. Observe the change in the graph response.

Pressing SW3 switch will return to streaming the raw data from the accelerometer.
